

Heat and Temperature

1. Define the following terms and include units:
 - a. Specific Heat
 - b. Latent Heat
2. Calculate the amount of energy that must be added to 100 g of water to raise the temperature from 10.0°C to 20.0°C.
3. Calculate how much energy must be added to 750 g of asphalt ($c = 920 \text{ J kg}^{-1} \text{ K}^{-1}$) to raise the temperature from 10.0°C to 20.0°C.
4. Calculate the change in temperature of 500 g of gold ($c = 130 \text{ J kg}^{-1} \text{ K}^{-1}$) when 5000 J of heat is added to the system.
5. When 10,000 joules of heat is added to 5 kg of a gas, its temperature increases by 10 C. Calculate the specific heat of the gas.
6. A 5 kg piece of steel ($c = 440 \text{ J kg}^{-1} \text{ K}^{-1}$) is heated by a 500.0 Watt heater for 5.0 minutes. The steel has an initial temperature of 15.0°C. Assume the heater is 100% efficient.
 - a. Calculate the amount of energy given to the steel in that time.
 - b. Calculate the final temperature of the steel.
7. Calculate how much energy it takes to melt 250 g of ice that was originally 273 K.
8. A 1500 kg car is stopped after initially traveling at 20 m/s. Assume that 75% of the energy lost is converted to heat in the car brakes.
 - a. Calculate the amount of heat gained by the brakes.
 - b. Assume each of the brakes on the front of the car have a mass of 9.5 kg and $c = 460 \text{ J kg}^{-1} \text{ K}^{-1}$. Calculate the temperature change in the brakes as a result of the braking.
 - c. Explain how cars keep their brakes from melting.
9. 200 g of water vapor at 373 K is condensing into water. Assuming the temperature does not change, calculate the amount of heat removed from the system.

10. Mercury was used in old thermometers. The typical mass was about 5 grams. The specific heat is $140 \text{ J kg}^{-1} \text{ K}^{-1}$.
- Calculate the amount of heat needed to increase the temperature of the thermometer from $20 \text{ }^\circ\text{C}$ to $38 \text{ }^\circ\text{C}$.
 - The alcohol that has often replaced mercury for use in thermometers has a specific heat of $2460 \text{ J kg}^{-1} \text{ K}^{-1}$. Assuming the properties of the glass container remain the same, describe one reason a mercury thermometer would be preferred over the alcohol thermometer.
11. A 10.0 g ice cube is initially $-5.0 \text{ }^\circ\text{C}$. Calculate the amount of energy required to completely melt the cube.
12. A Cast iron factory uses a $250,000 \text{ Watt}$ heater to melt their raw cast iron. The latent heat of fusion for cast iron is $126,000 \text{ J K}^{-1}$ and the specific heat of cast iron is $460 \text{ J kg}^{-1} \text{ K}^{-1}$. Assume 1000 kg of cast iron is heated at a time.
- The cast iron starts at room temperature (25°C). The heater initially heats the metal to its melting point (1200°C). Calculate the amount of heat required for this temperature change.
 - Upon reaching 1200°C , the heater begins to melt the cast iron. Calculate the amount of heat required to completely melt the cast iron.
 - Calculate the time required for the heater to completely melt the cast iron starting from room temperature.
13. In the morning, a lake is typically colder than the surrounding air. In the evening, the water is typically warmer than the surrounding air. Describe a reason why this would be true.
